CHLOROSTREP

The clinical use of Chlorostrep capsules has established Chloramphenicol as an effective antibiotic of ample bacterial spectrum in the group of infections caused by rickettsia and psittacosis lymphogranuloma.

Its large antimicrobial activity penetrates the tissue barrier and expands thru them very quickly, as well as in the body fluids and the spinal fluid.

Streptomycin is clinically indicated in infections caused by susceptible organisms. Orally administered its absorption is minimal even though large amounts go through the intestinal tract in high concentrations.

Chlorostrep capsules is a combination of chloramphenicol and streptomycin; each capsule contains 125 mg. of Ch. and 125 mg. of streptomycin as sulfate.

Indications:

Ch. is a potent therapeutic agent. It should be used under a physician's directions and should not be used for trivial infections. It is specially indicated for bacterial meningitis, typhoid fever, rickettsia, bacteroid infections and intraocular infections; septicemia due to gram negative organisms and other serious infections where bacteriologic or clinic evidence determine the ch. as the appropriate antibiotic.

The streptomycin used orally is not systematically absorbed and passes thru the intestine in high concentrations, many pathogen bacteria including shigellas and the coli group, are susceptible to its bactericide action.

Ch. is used successfully in the pre-operative stage of rectal or colon surgery, mixed infections found in intestinal surgery, anal-rectal tuberculosis, anal fistulas, cysts and pilonidal infections as well as enteric or diarrhea infections.

Precautions:

Ch. should be used under physician's instructions. It should not be used for trivial infections.

~~Serious~~ Blood dyscrasias including aplastic anaemia have been associated on rare occasions to the use of ch. When a long or repeated treatment is necessary, blood tests should be done at regular intervals.
