

...as demonstrated by
excretion studies in test animals

Urinary excretion study* indicates significantly greater G.I. absorption of Vibramycin—the percentage of the oral dose recovered in urine of mice relative to the amount recovered after an I.V. dose is 3.3-5.4 times greater than these other tetracyclines. Oral and I.V. doses were equivalent.

*During passage through the body a fraction of each antibiotic is metabolized, thus lowering the amount of active antibiotic recoverable after an oral dose.
